AB      . . . of tremor was proportional to the level of co-contraction.
Clinically, the tremor induced by repetitive TMS appeared very similar to
cerebellar tremors. In order to confirm this we
investigated two cerebellar patients, one with autosomal dominant
cerebellar ataxia and the other with. . . frequency of repetitive
TMS-induced tremor was independent of stimulus parameters, we conclude
that it represents some intrinsic property of the CNS. We
suggest that the tremor is caused by disruption of cortical processes
involved in terminating a voluntary movement or maintaining. . . with
adaptive cerebellar afferent inflow to motor cortex. Repetitive
TMS-induced tremor, therefore, may represent a model of some forms of
cerebellar tremor in man.

AB . . . overreaching (overstepping) and hypometria is underreaching (understepping). Tremor refers to an involuntary, rhythmic, oscillatory movement of a body part. The **tremor** of **cerebellar** disease typically is exaggerated by goal-oriented movements (intention **tremor**). **Cerebellar** lesions also often cause loss of the menace response, despite the presence of normal vision. The anatomic basis for this. . . be discussed here. Neurologic signs of cerebellar involvement also may be seen in association with those diseases that affect the **CNS** multifocally. In these cats, there may be additional signs indicating involvement of other anatomic areas or the cerebellar deficits may. . .

AB Infection of cattle with various stocks of *Trypanosoma brucei rhodesiense* indicated that 49% developed a fatal CNS disease comparable to that found in man. Duration of disease ranged from 85 to 1613 days post infection. All eight stocks of *T. b. rhodesiense* tested, including those from Ethiopia and Tanzania, induced CNS disease. Blood became positive three to five days after inoculation, and after an initial peak of parasitaemia remained positive for. . . subsequently became negative, although trypanosomes persisted in the lymph nodes for at least 56 to 1613 days. Only animals with CNS disease had detectable parasites in the CSF, usually after the animals had undergone severe deterioration. At post mortem examination trypanosomes. . . be found in the lymph nodes and CSF, and occasionally in the blood. Clinical signs included fever, hyperkinesia, weight loss, **cerebellar** ataxia, **tremor**, salivation and hyperaesthesia. A mild to moderate anaemia accompanied a transient thrombocytopenia and leucopenia. Animals subsequently developed leucocytosis. A pleocytosis. . .

AB We report here the clinical features of 3 affected siblings and neuropathological findings of the CNS from an autopsied case among them. Their common clinical features consisted of **cerebellar** ataxia and **tremors** through movements and postures. Two of the 3 siblings showed autonomic abnormalities, hard-of-hearing, pyramidal sign and areflexia. Then they always. . .

 AB . . . fatigue, nervousness, memory complaints, and sleepiness in the exposed group. In addition, we saw other neurologic signs, such as postural tremor, cerebellar signs, and bradykinesia, although without statistical significance. The data suggest that occupational exposure to pesticides containing Mn is a possible source of Mn intoxication of the CNS.
